This page by Professor Hans Reich (UW-Madison) provides some common reactive intermediates in Organic Chemistry such as compounds used in 1,3-dipole reactions, typical cations, anions, radicals, carbenes, and ylides.

Reactive Intermediates - Organic Chemistry Data & Info

a reactive intermediate is a short-lived, high-energy, highly reactive molecule. When generated in a chemical reaction, it will quickly convert into a more stable molecule. Only in exceptional cases can these compounds be isolated and stored (e.g., low temperatures, matrix isolation). When their existence is indicated, reactive intermediates can help explain how a chemical reaction takes place.

Reactive Intermediates - Chemistry LibreTexts

In the course of these multi-step reaction sequences, short-lived intermediates can be generated that quickly convert into other intermediates, reactants, products or side products. As these intermediates are highly reactive, they cannot usually be isolated, but their existence and structure can be proved by theoretical and experimental methods.

Carbocations are reactive intermediates in many organic reactions. This idea, first proposed by Julius Stieglitz in 1899,[10] was further developed by Hans Meerwein in his 1922 study[11][12] of the Wagner-Meerwein rearrangement.

5.8 Reactive Intermediates - Radicals - Chemistry LibreTexts

An intermediate or reaction intermediate is a substance formed during a middle step of a chemical reaction between reactants and the desired product. Intermediates tend to be extremely reactive and short-lived, so they represent a low concentration in a chemical reaction compared with the amount of reactants or products.

Six-electron, neutral, monovalent, highly reactive intermediates. The N atom has 4 non-bonded electrons. There are triplet and singlet states, as for carbenes. They are isoelectronic with carbenes, but have 6 π electrons instead.

It is important to know the hierarchy of Reaction Intermediates such as Radicals, Carbocations, Carbanions. Here we present a quick guide to Reaction Intermediate hierarchies. The Big Picture: Radicals and Carbocations prefer a greater degree of alkyl substitution.

A reaction intermediate or an intermediate molecular entity (atom, ion, molecule..) with a lifetime appreciably longer than a molecular vibration that is formed (directly or indirectly) from the reactants and reacts further to give (either directly or indirectly) the products of a chemical reaction. In organic chemistry, a carbanion (referred to as a carbonium ion in some texts) is a reaction intermediate in which there is a negative one charge located on a carbon atom. Carbanions are formed...

What is a Reaction Intermediate? - Definition & Examples ...

Often, reactive intermediates such as carbocations and free radicals have more delocalized structure than their parent reactants, giving rise to unexpected products. The classical example is allylic rearrangement. When 1 mole of HCl adds to 1 mole of 1,3-butadiene, in addition to the ordinarily expected product 3-chloro-1-butene, we also find 1 ...

Resonance (chemistry) - Wikipedia

A reaction intermediate or an intermediate is a molecular entity that is formed from the reactants (or preceding intermediates) and reacts further to give the directly observed products of a chemical reaction. Most chemical reactions are stepwise, that is they take more than one elementary step to complete.
